# Learn Nodes

Node: An individual part of a larger data structure

Nodes are a basic data structure which contain data and one or more links to other nodes. Nodes can be used to represent a tree structure or a linked list. In such structures where nodes are used, it is possible to traverse from one node to another node.

Null node link

Data structures containing nodes have typically two bits of information stored in a node: data and link to next node. The first part is a value and the second part is an address of sorts pointing to the next node. In this way, a system of nodes is created. A `NULL` value in the link part of a node's info denotes that the path or data structure contains no further nodes.

Orphaned nodes

Nodes that have no links pointing to them except for the head node, are considered "orphaned." In the illustration, if the nodes `a2` and `a5` are removed, they will be orphaned.
Python Node implementation

A Node is a data structure that stores a value that can be of any data type and has a pointer to another node. The implementation of a Node class in a programming language such as Python, should have methods to get the value that is stored in the Node, to get the next node, and to set a link to the next node.

```python
class Node:
  def __init__(self, value, next_node=None):
    self.value = value
    self.next_node = next_node

  def set_next_node(self, next_node):
    self.next_node = next_node

  def get_next_node(self):
    return self.next_node

  def get_value(self):
    return self.value
```
